**ON THE COVER**

Ebola virus enters into  
cells in small vesicles  
called endosomes.  
Virus eventually moves  
into endosomes that  
have both NPC1 (dark  
blue rods) and TPC2  
(yellow spikes) proteins  
on their membranes

and then into vesicles with TPC2 only. By  
disrupting the function of TPC2 with drugs,  
the virus is locked into the endosome,  
unable to be released to infect the cell. See  
pages 947 and 995. *Illustration: Valerie
